Server Diagram

The controller located in `listings.server.controller` defines the functions that the router calls when the server makes get, put and post requests. These functions hold the code for querying the mongoose database to interact with the data itself, such as creating, updating, deleting and retrieving listings.

The router specifies where get, post, and put requests are called from. When a get request is processed, the router sends the request to the `listings.list` function in the controller, which holds the code for the request.

Middleware is used throughout the code to connect the router calls and the controller functions, allowing the router to call functions before reaching the final request handler. This is implemented with the `listing` property when you bind it with the request object.
